The Director of the United States Patent and Trademark Office

Has received an application for a patent for a new and useful invention. The title and description of the invention are enclosed. The requirements of law have been complied with, and it has been determined that a patent on the invention shall be granted under the law.

Therefore, this

United States Patent

Grants to the person(s) having title to this patent the right to exclude others from making, using, offering for sale, or selling the invention throughout the United States of America or importing the invention into the United States of America, and if the invention is a process, of the right to exclude others from using, offering for sale or selling throughout the United States of America, or importing into the United States of America, products made by that process, for the term set forth in 35 U.S.C. 154(a)(2) or (c)(1), subject to the payment of maintenance fees as provided by 35 U.S.C. 41(b). See the Maintenance Fee Notice on the inside of the cover.

David J. Kappos

Director of the United States Patent and Trademark Office
ABSTRACT

A TiO₂—SiO₂ aerogel and TiO₂—SiO₂ aerogel monolith with a regular and predeterminable shape and an ordered mesoporosity and a method of making the aerogel and aerogel monolith, using surfactants in preparing the SiO₂ sol before mixing with TiO₂ sol. The aerogel obtained by this method has a specific surface area greater than 400 m²/g and a pore volume larger than 0.5 cc/g.

TITANIA-SILICA AEROGEL MONOLITH WITH ORDERED MESOPOROSITY AND PREPARATION THEREOF

FIELD OF THE INVENTION

The present invention relates to TiO₂—SiO₂ aerogel and the process of producing it. Particularly, it relates to a freestanding monolithic TiO₂—SiO₂ aerogel with an ordered mesoporosity.

BACKGROUND OF THE INVENTION

Aerogel is a solid with a porous, sponge-like structure in which about 95% of the volume is empty space (that is, filled with air). Aerogels are therefore unique among solid materials. They possess extremely low densities, large open pores, and a large inner surface area. Discovered in the 1930s, aerogel is believed to be the world’s lightest solid.

Aerogel thus possesses interesting physical and chemical properties including extremely low thermal conductivity, low sound velocity combined with excellent thermostability and mechanical properties. For silica aerogel, it also possesses high optical transparency. Currently, the aerogel materials are widely applied in the catalytic reactions, aerospace technology (storage, thickening or transport of rocket fuels and consisting of outside layer of spacecraft), advanced materials and so on. For example, Monsanto once produced aerogel granules made of silica for use as additives in cosmetics and toothpastes. NASA has used aerogels as insulation on the Mars Sojourner robot and as a medium to capture pure star dust, which was then returned to Earth for study.

Generally, the aerogels are prepared from molecular precursors via sol-gel method and following supercritical drying processing to exchange the pore liquid with air while maintaining the filigrane solid network. (Gesser, H. D.; Goswami, P. C. Chem. Rev., 89, (1989), 765; Hüssing, N.; Schubert, U. Angew. Chem. Int. Ed., 37, (1998), 22.; Pierre, A. C.; Pajonk, G. M. Chem. Rev., 102, (2002), 4243.) By increasing the temperature and the pressure on the gel so that the liquid inside becomes “supercritical,” a special state in which a material has some properties of a liquid and some properties of a gas. Interestingly, supercritical liquid, like a gas, has practically no surface tension. The surface tension is believed to be the reason that causes collapse of the scaffolding made of the tiny network inside the gel as the liquid evaporates.

With the above basic approach, it is no longer difficult to make aerogels. Aerogels generally assume two physical forms: powder form (without defined shape) and monolithic form (with defined shapes). While it is relatively easy to make monolithic aerogels which are predominantly based on SiO₂, there is no known easy procedure to make monolithic aerogels out of material that contains a substantial amount of non SiO₂ components. In addition, aerogels tend to have a broad pore size distribution. Aerogels that are not purely made from SiO₂ are useful for many applications, for example, for embedding catalysts therein for increasing catalytic efficiency due to aerogels’ large surface mass ratio wherein monolithic aerogels are advantageous than aerogel in powder form. The monolithic form prevents the nanoparticles from delamination, in particular, in the field of indoor air quality control by gas-phase photocatalytic oxidation reaction. Furthermore, catalysts embedded in monolithic aerogel help to overcome the practical drawbacks of the fine powders, including the difficult separation and handling for liquid-phase reactions or large pressure drops for gas phase reactions. Therefore, there is a great need for developing aerogel monolith not purely based on SiO₂ as well as novel procedures to make such aerogel monolith easily and economically.

SUMMARY OF THE INVENTION

Accordingly, an object of the present invention is to provide a monolithic TiO₂—SiO₂ aerogel and a method of fabricating thereof. A further object of the present invention is to provide a TiO₂—SiO₂ aerogel which has an ordered mesoporosity.

In order to achieve these and other objects of the invention, a TiO₂—SiO₂ aerogel according to one aspect of the present invention has the following features: (1) containing at least 0.1% w/w of titania, preferably 1%-99%, most preferably 5%-50%; (2) having an ordered mesoporosity, with pore diameters varying between 2-50 nm; and (3) a regular shape, which may be any defined 3-dimensional shapes with a plurality of flat or curved surfaces, such as sphere, pyramid, cube, elongated cube, cylinder, sheet object with a predetermined thickness, etc.

According to another aspect of the invention, in the TiO₂—SiO₂ aerogel between 5% and 50% of the titania is in the form of titanium dioxide crystals, and at least 50%, preferably 80%, of the titanium dioxide crystals have a size between about 3 nm and about 25 nm and a crystallinity greater than 70%.

According to another aspect of the invention, the TiO₂—SiO₂ aerogel includes a Ti—O—Si bond, which is characterized by an absorption peak around 960 cm⁻¹ in the infrared spectrum.

According to another aspect of the invention, the TiO₂—SiO₂ aerogel has a specific surface area greater than 200 m²/g, preferably greater than 400 m²/g, and a pore volume larger than 0.25 cc/g, preferably larger than 0.5 cc/g.

According to another aspect of the invention, in the TiO₂—SiO₂ aerogel at least 65% of said titanium dioxide crystals are substantially pure anatase, brookite or rutile. As another aspect of the present invention, there is provided a process for fabricating a TiO₂—SiO₂ aerogel monolith, which includes the following steps:

a) forming a titanium dioxide sol with particle size of about 3 nm-25 nm, preferably, by hydrolyzing a titanium dioxide precursor in the presence of alcohol and water and then peptizing using an acid, which can be, for example, HNO₃, H₂SO₄, HCl or H₃PO₄; other acids may also provide satisfactory results; alternatively, the titanium dioxide sol is prepared by mixing an organic modifier (such as, for example, ketone) with a titanium dioxide precursor, such as titanium isopropoxide, at a molar ratio ranging from 1:10 to 10:1;

b) forming a silica sol with particle size of about 3 nm-25 nm (as measured by AFM), preferably by hydrolyzing a silica precursor, such as, for example, tetraethyl orthosilicate or tetramethyl orthosilicate, in the presence of alcohol and water and then peptizing using an acid, which can be, for example, HNO₃, H₂SO₄, HCl or H₃PO₄; other acids may also provide satisfactory results;

c) optionally adding one or more surfactants to said silica sol to form a mixture where said surfactant or surfactants account for 50%-70% by weight, wherein the surfactant or surfactants can be one or more of long chain organic ammonium salt, amphiphilic block copolymer, cetetyltrimethyl ammonium salt, and poly(ethylene oxide-poly(propylene oxide-poly(ethylene oxide), preferably cetetyltrimethyl ammonium bromide or poly(ethylene oxide)-poly(propylene oxide)-poly(ethylene oxide));
d) mixing the titanium dioxide sol with the silica sol of step (2) or with the mixture of step (c) to afford a TiO$_2$—SiO$_2$ sol; e) transferring an amount of TiO$_2$—SiO$_2$ sol into a mold, which can be of any suitable shapes; f) allowing said TiO$_2$—SiO$_2$ sol to undergo a gelation process to afford an allogel; g) drying said allogel under supercritical conditions to afford an aerogel; h) calcining the aerogel to afford final TiO$_2$—SiO$_2$ aerogel monolith with a regular shape predetermined through the design of the mold in step (e).

It is understood that one or more features according to various aspects of the present invention may be present in a particular embodiment of the invention and the particular embodiment may not necessarily possess all the features listed above.

The various features of novelty which characterize the invention are pointed out with particularity in the claims annexed to and forming a part of this disclosure. For a better understanding of the invention, its operating advantages, and specific objects attained by its use, reference should be made to the drawings and the following description in which there are illustrated and described preferred embodiments of the invention.

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 is a schematic diagram illustrating the steps for making TiO$_2$—SiO$_2$ aerogel monolith samples of the present invention.

FIG. 2 is the XRD results of TiO$_2$—SiO$_2$ aerogels with titania content of (a) 50 wt %, (b) 10 wt %, and (c) 5 wt % after ethanol supercritical drying.

FIG. 3 is the XRD results of TiO$_2$—SiO$_2$ aerogels with titania content of (a) 50 wt %, (b) 10 wt %, and (c) 5 wt % after ethanol supercritical drying and followed by 450°C calcination.

FIG. 4 is the XRD pictures of titania-silica samples prepared by the direct calcination method.

FIG. 5 is an FT-IR spectrum of TiO$_2$—SiO$_2$ aerogel monolith sample.

FIG. 6 is an XRD result of surfactant incorporated TS-50 aerogel monolith.

FIG. 7 is a TEM image of surfactant incorporated TS-50 aerogel monolith.

FIG. 8 is a TEM image of surfactant-free TS-50 aerogel monolith.

FIG. 9 is a schematic diagram of the photoreactor and the test setup.

**DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT**

Preparation of TiO$_2$—SiO$_2$ Aerogel Monolith

FIG. 1 is a schematic diagram illustrating the process for making TiO$_2$—SiO$_2$ aerogel monolith samples as one particular embodiment of the present invention. As shown, the process can be divided into 5 steps. Step 1 involves hydrolysis and peptization to produce a stable titanium dioxide sol (A) where a solution of precursor (for example, titanium isoproxide) and alcohol (e.g. ethanol) are mixed with distilled deionized water and nitric acid. In the parallel step 1', a stable SiO$_2$ sol (B) is produced by the acidic hydrolysis of a mixture containing a predetermined molar ratio of TEOS, H$_2$O, HNO$_3$, ethanol and surfactant. In step 2, (A) and (B) are mixed to obtain a TiO$_2$—SiO$_2$ sol (C). In step 3, a predetermined amount of TiO$_2$—SiO$_2$ sol (C) is placed in a mold with a desired shape and stay without agitation for a period of time until gelation occurs, whereby forming an allogel (D). In step 4, the ethanol or CO$_2$ supercritical drying is performed to prepare TiO$_2$—SiO$_2$ aerogel (E), which is further calcined in step 5 to yield the final TiO$_2$—SiO$_2$ aerogel monolith (F).

The following are detailed descriptions of the embodiment with relevant specifics, which are provided as example only and may be varied through routine optimization by those with ordinary skill in the art.

I. Preparation of TiO$_2$ sol (A):

1) 4 ml of TIP (titanium isoproxide, 98%) was added into 60.8 ml of ethanol (99.9%) solution and stirred for 10 min. Other titanium compounds may also be used to prepare TiO$_2$ sol, such as, for example, titanium (IV) butoxide, titanium ethoxide, titanium methoxide and titanium stearate. n-butanol may replace ethanol and provide satisfactory results.

2) 1 ml of nitric acid (2.5M) was then used for peptization of the above TIP solution to prepare stable and clear TiO$_2$ sol (A) in a process in which titanium isoproxide hydrolyzed to form a mixture of (Ti(OH)$_3$) where X=2-0, Y=4-2X.

II. Preparation of SiO$_2$ Sol (B):

1) TEOS (tetraethyl orthosilicate, 98%), distilled deionized water, HNO$_3$ and ethanol were mixed according to a molar ratio of 1:8:0.08:3.8 and stirred vigorously.

2) The solution was refluxed at 55°C for 6 hours to obtain clear SiO$_2$ solution (B').

III. Preparation of Surfactant Incorporated SiO$_2$ Sol (B)

1) TEOS (tetraethyl orthosilicate, 98%), distilled deionized water, HNO$_3$ and ethanol were mixed according to a molar ratio of 1:8:0.08:3.8 and stirred vigorously.

2) The solution was refluxed at 55°C for 6 hours to obtain clear SiO$_2$ solution.

3) About 5 g of a surfactant (Pluronic, 123 surfactant (EO)$_{10}$PO$_{30}$(EO)$_{10}$) was added into above SiO$_2$ and stirred until all the surfactant dissolved completely.

IV. Preparation of TiO$_2$—SiO$_2$ Aerogel Monolith by Ethanol Supercritical Drying:

1) SiO$_2$ sol (B') and TiO$_2$ sol (A) were mixed at a predetermined ratio and stirred for 0.5 hour to obtain a homogeneous TiO$_2$—SiO$_2$ mixed sol (C). The SiO$_2$ sol (B') and TiO$_2$ sol (A) may be mixed at a ratio to achieve a desired titania content, for example, 50%, 10%, 5% of TiO$_2$ by weight in the final monolith. However, other TiO$_2$ percentages may also produce satisfactory results.

2) 5 ml of TiO$_2$—SiO$_2$ sol was transferred into a mold, which had a desired shape.

3) The mold was sealed to prevent organic evaporation.

4) Gelation occurred within several hours or days, depending on the titania content, to form an allogel (D).

5) The allogel (D) was removed from the mold and put into a holder.

6) The holder was placed into an autoclave made of 316 stainless steel, and then an excess amount (80 ml) of anhydrous ethanol was added into the autoclave.

7) The autoclave was purged by pure N$_2$ gas with well sealing and then heated to 270-290°C. In 3-5 hours. The final pressure was controlled to 1400-1700 psi by releasing a small amount of ethanol during the heating process.

8) After stabilizing for about half an hour, the ethanol was slowly evacuated at the rate of 500-600 psi/h.

9) When the internal pressure reached ambient pressure, heating was continued for 2-4 hours and then the autoclave was purged by pure N$_2$ gas to drive off the residue ethanol vapor in the system.

10) The autoclave was slowly cooled down to room temperature overnight.
11) The obtained aerogel sample (E) was calcined at 450°C for 5 hours to produce the aerogel monolith (F).

VI. Preparation of Surfactant Incorporated TiO2—SiO2 Aerogel Monolith by Ethanol Supercritical Drying:
The steps involved are substantially the same as those described in IV, except that a surfactant incorporated SiO2 sol (B) was used in place of a SiO2 sol (B').

VI. Preparation of TiO2—SiO2 Aerogel Monolith by CO2 Supercritical Drying:
1) SiO2 sol (B') and TiO2 sol (A) were mixed at a predetermined ratio and stirred for 0.5 hours to form a homogeneous TiO2—SiO2 mixed sol (C). The SiO2 sol (B') and TiO2 sol (A) may be mixed at a ratio to achieve a desired titania content, for example, 50%, 10%, 5% of TiO2 by weight in the final monolith. However, other TiO2 percentages may also produce satisfactory results.
2) 1 ml of TiO2—SiO2 sol was transferred into a mold.
3) A parafilm was used for seal to prevent organic evaporation.
4) Gelation occurred within several hours or days, depending on the titania content, to form an aerogel (D).
5) The formed aerogel was removed from the mold and put into a drying chamber.
6) Liquid CO2 was dosed into the chamber and exchanged with ethanol in the aerogel for several hours or days. During this extraction period, the chamber was refilled with fresh liquid CO2 several times.
7) The chamber temperature was raised to 50°C in 1-2 hours and then kept at 50°C for 1 hour.
8) Outlet valve was opened and pressure was slowly released in several hours to ambient pressure.
9) The chamber was slowly cooled down to room temperature overnight.

10) The obtained aerogel sample was calcined at 450°C for 5 hours to produce the aerogel monolith.

VII. Preparation of Surfactant Incorporated TiO2—SiO2 Aerogel Monolith by CO2 Supercritical Drying:
The steps involved are substantially the same as those described in VI, except that a surfactant incorporated SiO2 sol (B) was used in place of a SiO2 sol (B').

VIII. Basic Synthesis of TiO2—SiO2 Aerogels by Ethanol Supercritical Drying:
1) TMOS-ethanol solution was prepared by dissolving tetramethyl orthosilicate (TMOS, 98%) in ethanol (99.9%) (TMOS:ethanol=1:10:2, molar ratio).
2) HNO3 solution was added into the TMOS-ethanol solution under strong stirring to at least partially hydrolyze TMOS (TMOS:H2O:HNO3=1:2:0.005, molar ratio). The mixture was stirred for 90 minutes at 50°C to speed up the hydrolysis process, and then cooled down to room temperature.
3) TIP-ethanol solution was prepared by dissolving titanium isopropanoxide (TIP, 98%) in ethanol (TIP:ethanol=1:2, molar ratio).
4) A reagent (acetylacetone) was added into the TIP-ethanol solution under strong stirring to adjust the hydrolysis rates of TIP in the presence of water (TIP:reagent=1:1, molar ratio). As heat was generated in this process, the solution was cooled down to room temperature.
5) The TIP solution of step (4) was added into the solution containing partially hydrolyzed TMOS of step (2) under strong stirring (TMOS:TIP=1:1, molar ratio). Then, an amount of ammonia solution was added into the mixture (TMOS:H2O:NH3=1:4:0.07, molar ratio).
6) An amount of the resulting mixture was transferred into a mold. Gelation occurred after several hours or days to form an aerogel. The aerogel (wet gel) was aged for several days before further treatment.
7) A TiO2—SiO2 aerogel of step (6) was removed from its mold and put into a drying chamber.
8) Liquid CO2 was introduced into the chamber and exchanged with ethanol in the aerogels for several hours or days. During this period, the chamber was refilled with fresh liquid CO2 several times.
9) The chamber temperature was raised to 50°C in 1-2 hours and then kept at 50°C for 1 hour.
10) Outlet valve was opened and the pressure was slowly released over a period of several hours to reach ambient pressure.
11) The chamber was slowly cooled down to room temperature overnight.
12) The TiO2—SiO2 aerogel could now be taken out of the chamber.

IX. Basic Synthesis of TiO2—SiO2 Aerogels by Hydrothermal Pretreatment and Followed by CO2 Supercritical Drying:
1) Tetramethyl orthosilicate (TMOS, Aldrich, 98%) in ethanol (Merck, 99.9%) was prepared (TMOS:ethanol=1:10:2, molar ratio).
2) HNO₃ solution was added into TMOS-ethanol solution under strong stirring to partially hydrolyze TMOS (TMOS: H₂O:HNO₃=1:2:0.005, molar ratio). The mixture was stirred for 90 min at 50°C to speed up the hydrolysis process, and then cooled down to room temperature.

3) Titanium isopropoxide (TIP, ACROS, 98%) in ethanol was prepared (TIP:ethanol=1:2, molar ratio).

A reagent (acetylacetone) was added into TIP-ethanol solution under strong stirring to adjust the hydrolysis rates of TIP at the presence of water (TIP:reagent=1:1, molar ratio). Heat was generated in this process and the solution was cooled down to room temperature.

The solution containing TIP was added into the solution containing partially hydrolyzed TMOS under strong stirring (TMOS:TIP=1:1, molar ratio). Then, a certain amount of ammonia solution was added into the mixture (TMOS:H₂O:NH₃=1:2:0.007, molar ratio).

The resulting mixture was transferred into molds. Gelation occurred after several hours or days. The alcopel (wet gel) was aged for several days before further treatment.

7) The obtained TiO₂—SiO₂ alcopel of step (6) was put in a TEFLOW liner filled with pure ethanol. The liner was sealed in a closed SS (stainless steel) container.

8) The SS container was put in a furnace and heated to a certain temperature (e.g., 200°C). After 10 hours, the container was taken out of the furnace.

9) The TiO₂—SiO₂ alcopelgs were taken out of the liner and stored in a container filled with pure ethanol before CO₂ extraction and supercritical drying.

10) Liquid CO₂ was introduced into the chamber and exchanged with ethanol in the alcopelgs for several hours or days. During this period, the chamber was refilled with fresh liquid CO₂ several times.

11) The chamber temperature was raised to 50°C in 1-2 hours and then kept at 50°C for one hour.

12) Outlet valve was opened and the pressure was slowly released over a period of several hours to reach ambient pressure.

13) The chamber was slowly cooled down to room temperature overnight.

14) The TiO₂—SiO₂ aerogel could now be taken out of the chamber.

I. Basic Synthesis of TiO₂—SiO₂ Aerogels by Microwave Pretreatment and Followed by CO₂ Supercritical Drying:

1) TMOS-ethanol solution was prepared by dissolving tetramethyl orthosilicate (TMOS, 98%) in ethanol (99.9%) (TMOS:ethanol=1:10.2, molar ratio).

2) HNO₃ solution was added into TMOS-ethanol solution under stirring to at least partially hydrolyze TMOS (TMOS:H₂O:HNO₃=1:2:0.005, molar ratio). The mixture was stirred for 90 minutes at 50°C to speed up the hydrolysis process, and then cooled down to room temperature.

3) TIP-ethanol solution was prepared by dissolving titanium isopropoxide (TIP, 98%) in ethanol (TIP:ethanol=1:2, molar ratio).

4) A reagent (acetylacetone) was added into the TIP-ethanol solution under strong stirring to adjust the hydrolysis rates of TIP in the presence of water (TIP:reagent=1:1, molar ratio). As heat was generated in this process, the solution was cooled down to room temperature.

5) The solution containing TIP of step (4) was added into the solution containing partially hydrolyzed TMOS of step (2) under strong stirring (TMOS:TIP=1:1, molar ratio). Then, a certain amount of ammonia solution was added into the mixture (TMOS:H₂O:NH₃=1:4:0.07, molar ratio).

6) An amount of the resulting mixture was transferred into a mold. Gelation occurred after several hours or days to form an alcopel. The alcopel (wet gel) was aged for several days before further treatment.

7) The obtained TiO₂—SiO₂ alcopel of step (6) was put in a TEFLOW liner filled with pure ethanol. The liner was sealed in a closed SS (stainless steel) container.

8) The SS container was put in a furnace and heated to a certain temperature (e.g., 200°C). After 10 hours, the container was taken out of the furnace.

9) The TiO₂—SiO₂ alcopelgs were taken out of the liner and stored in a container filled with pure ethanol before CO₂ extraction and supercritical drying.

10) Liquid CO₂ was introduced into the chamber and exchanged with ethanol in the alcopelgs for several hours or days. During this period, the chamber was refilled with fresh liquid CO₂ several times.

11) The chamber temperature was raised to 50°C in 1-2 hours and then kept at 50°C for one hour.

12) Outlet valve was opened and the pressure was slowly released over a period of several hours to reach ambient pressure.

13) The chamber was slowly cooled down to room temperature overnight.

14) The TiO₂—SiO₂ aerogel could now be taken out of the chamber.
12) Outlet valve was opened and the pressure was slowly released in several hours to reach ambient pressure.
13) The chamber was slowly cooled down to room temperature overnight.
14) The TiO₂—SiO₂ aerogel could now be taken out of the chamber.

Properties of the TiO₂—SiO₂ Aerogel Monolith Samples
Aerogel Shape and Volume Observation:
Although the aerogel monolith sample produced as a particular embodiment of the present invention has a smaller volume and diameter than that of the corresponding algel (with about 5%-40% shrinkage), it maintains its regular shape without any crack after ethanol supercritical drying and subsequent calcination, indicating that the process of the present invention enables preparation of crack-free TiO₂—SiO₂ aerogel monolith.

X-ray Diffraction Analysis:
The aerogel monolith sample was ground and shifted to produce a fine powder. The powder was placed in an aluminum holder, which is then placed in the sample holder of the X-ray diffractometer. A CuKα X-ray source was used and the X-ray diffraction was recorded for 20°<2θ<60° by step-scanning at 0.05° increments.
As shown in FIG. 2, the samples gave the characteristic diffraction of anatase which peaks at 20 values around 25°, 38°, 47° and 54° for every sample, and the intensity of anatase diffraction peak drops gradually with the increasing of the SiO₂ content. In the case of TS-5 aerogel sample (5% titania content), only a small anatase diffraction peak can be observed. After calcination at 450°C, the aerogel monolith samples (shown in FIG. 3) exhibit sharper anatase peaks as compared to those un-calcined ones (shown in FIG. 2). Comparatively, TiO₂—SiO₂ samples prepared by direct calcination method without pre-supercritical drying only show amorphous crystal phase (shown in FIG. 4). These results mean that ethanol supercritical drying process enables the production of nano-sized anatase crystals in the SiO₂ network. This effect can not be achieved with the CO₂ supercritical drying procedure.

BET Surface Area Measurement:
The BET surface area and pore volume of the aerogel are measured by nitrogen physisorption. The capped quartz tube sample holder from Coulter SA 3 100 nitrogen physisorption apparatus was weighted. About 0.1 gram of the aerogel powder was measured and placed inside the quartz tube sample holder. The capped quartz tube sample holder (with the sample) was weighed again. The holder was then connected to the out-gassing port of the Coulter SA 3100. The sample was outgassed at a desired temperature at 250°C for 2 hours. After outgassing and nitrogen physisorption conducted at 77 K, the capped quartz tube sample holder (with outgassed sample) was weighted again to calculate the physisorption data, from which the BET surface area and pore volume were obtained.

Table 1 summarizes the results of nitrogen sorption analysis of TiO₂—SiO₂ samples prepared by different methods. The aerogels prepared with supercritical drying and calcination at both temperatures, have larger specific surface areas and pore volumes. The macropore appears when the titania content attains 50 wt% in the aerogel series. Addition of surfactant in the aerogel has positive effect on the sample's pore volume and BET surface area. Comparatively, normal preparation method (i.e. direct calcination) can only produce microporous materials. The results indicate that the ethanol supercritical drying process affects not only the crystal phase, but also the pore geometry.

*surfactant incorporated aerogel sample.
**Aerogel sample produced via normal preparation method (i.e. direct calcination)
S-TS-5, TS-10, and TS-50 aerogel samples contain 5%, 10%, and 50% of TiO₂ by weight in the final dried monolith, respectively.

Fourier Transform Infrared Spectroscopic Analysis:
About 10 mg of potassium bromide (reference sample) was placed on the sample holder of a diffuse reflectance infrared Fourier transform spectroscopic (DRIFTS) cell. The cell was positioned in a Fourier Mantis mirror assembly (Harrick) and placed in the Perkin Elmer Spectrum GX FTIR (Fourier Transformation Infrared Spectroscopy). The chamber of the FTIR was purged with dry, carbon dioxide free air until the signal stabilized in about 15 minutes. Reflectant mode of the FTIR was used to observe the background signal.

Using the same procedure as described above in connection with the reference sample, approximately 0.05 g aerogel sample was used with the FTIR to record the spectrum at room temperature. The aerogel sample was scanned from 450 cm⁻¹ to 4000 cm⁻¹ at a resolution of 1 cm⁻¹ and 250 scans were collected. FIG. 5 shows the FT-IR spectrum of TiO₂—SiO₂ aerogel monolith. The peak located at 960 cm⁻¹ ascribing to Ti—O—Si bond, which can be observed after ethanol supercritical drying.

FIG. 6 and FIG. 7 are the small angle XRD result and TEM photo of surfactant incorporated TS-50 aerogel monolith, respectively. As seen in FIG. 7, the TEM photo shows well-ordered hexagonal arrays of mesopores. This result is confirmed by small angle XRD analysis (see FIG. 6) which shows a diffraction peak at around 0.8 degree ascribing to ordered hexagonal pore arrangement with (100) orientation. By comparison, the TEM photo of surfactant-free aerogel monolith, seen in FIG. 8, only shows nano-sized particles rather than ordered pore geometry.

The Catalytic Activity of the TiO₂—SiO₂ Aerogel Monolith
Photocatalytic oxidation reaction catalyzed by TiO₂—SiO₂ aerogel monolith was analyzed in a flow reactor. As shown in FIG. 9, the flat, rectangular photo-reactor had dimensions of 578 mm x 113 mm. The stainless steel reactor has the inlet and outlet ports, a recess for the catalyst plate and two sets of machined baffles. A 6.25 mm thick Pyrex glass cover completes the reactor assembly. The Pyrex glass window and the stainless steel reactor form a narrow rectangular channel (2 mm deep x 112 mm wide) for gas flow.

Liquid VOC (Volatile organic compounds) was delivered to a constant temperature heat exchanger using a syringe pump 5 (kdScientific 1000) and mixed with synthetic air before entering the reactor 6. The TiO₂—SiO₂ aerogel monolith (diameter: 12 mm, weight: 0.137 g) was on the stainless steel plate located 322 mm downstream from the inlet port.
(gas entrance). In a typical experiment, a metered amount of the VOC vapor (0.01 ml/h) was mixed with pure synthetic air with flow rate at 400 ml/min before entering the reactor. After the feed concentration attained equilibrium, the aerogel monolith was illuminated by five fluorescent black lamps (365 nm, 6 W) located 10 mm above reactor’s window.

The gases from the outlet port were separated using a GS-Gaspro capillary column and analyzed using a gas chromatograph (HP 6890) equipped with thermal conductivity and flame ionization detectors. The gases used in the GC were helium (UHP, CW), hydrogen (UHP, HKO) and synthetic air (HP, TIKSP).

The catalytic activity of the TiO₂—SiO₂ aerogel monolith sample prepared according to the previous section under “VII. Basic synthesis of TiO₂—SiO₂ aerogels by ethanol supercritical drying” was investigated using gas-phase trichloroethylene (TCE) and isopropanol (IPA) as probe molecules, respectively. Table 2 shows the photocatalytic degradation results. It indicates that the TiO₂—SiO₂ aerogel aerogel is capable of degradation of VOCs under the UV illumination condition.

Table 2: Photocatalytic degradation results

Day air flow rate: 400 ml/min (for TCE) and 200 ml/min (for IPA)
TCE inlet concentration: 137 ppm
Isopropanol inlet concentration: 266 ppm

While there have been described and pointed out fundamental novel features of the invention as applied to a preferred embodiment thereof, it will be understood that various omissions and substitutions and changes, in the form and details of the embodiments illustrated, may be made by those skilled in the art without departing from the spirit of the invention.

What is claimed is:

1. A TiO₂—SiO₂ aerogel monolith, comprising:
   - at least 0.1% w/w of titania;
   - a regular shaped TiO₂—SiO₂ aerogel monolith; and
   - a Ti—O—Si bond in said aerogel,
   wherein said bond has an absorption peak around 960 cm⁻¹ in an infrared spectrum.

2. The TiO₂—SiO₂ aerogel monolith of claim 1, further comprising an ordered mesoporosity with a pore diameter range of 2-50 nm and where at least 10% of said titania is in the form of titanium dioxide crystals.

3. The TiO₂—SiO₂ aerogel monolith of claim 2, wherein said regular shape is sphere, pyramid cube, elongated cube, cylinder, sheet or supported film with a thickness.

4. The TiO₂—SiO₂ aerogel monolith of claim 2, wherein said regular shape is a block with a plurality of flat or curved sides.

5. The TiO₂—SiO₂ aerogel monolith of claim 2, wherein said titanium dioxide crystals have a size between about 3 nm and about 25 nm and a crystallinity greater than 70%.

6. The TiO₂—SiO₂ aerogel monolith of claim 2, wherein said titania accounts for 1%-99% by weight and at least 30%-50% of said titania is in the form of titanium dioxide crystals.

7. The TiO₂—SiO₂ aerogel monolith of claim 2, wherein said aerogel has a specific surface area greater than 400 m²/g and a pore volume larger than 0.5 cc/g.

8. The TiO₂—SiO₂ aerogel monolith of claim 6, wherein at least 65% of said titanium dioxide crystals are selected from the group consisting of anatase, brookite and rutile.

9. A process of fabricating a TiO₂—SiO₂ aerogel monolith, comprising the steps of:
   (a) forming a titanium dioxide sol with particle size of about 3 nm-25 nm;
   (b) forming a silica sol with particle size of about 3 nm-25 nm;
   (c) adding one or more surfactants to said silica sol to form a mixture where said surfactant or surfactants account for 50%-70% by weight;
   (d) mixing said titanium dioxide sol with said mixture of step (c) to afford a homogenous TiO₂—SiO₂ sol;
   (e) transferring an amount of said TiO₂—SiO₂ sol into a mold;
   (f) allowing said TiO₂—SiO₂ sol to undergo a gelation process to afford an aerogel; and
   (g) drying said aerogel under ethanol supercritical conditions to afford an aerogel.

10. The process of claim 9, wherein said aerogel is further calcined to afford a final TiO₂—SiO₂ aerogel monolith.

11. The process of claim 10, wherein said titanium dioxide sol is prepared by hydrolyzing a titanium dioxide precursor in the presence of alcohol and water and then peptizing using a first acid.

12. The process of claim 11, wherein said silica sol is prepared by hydrolyzing a silica precursor in the presence of alcohol and water and then peptizing using a second acid.

13. The process of claim 12, wherein said first acid and second acid are independently selected from the group consisting of HNO₃, H₂SO₄, HCl and H₃PO₄.

14. The process of claim 12, wherein said silica precursor is tetraethyl orthosilicate or tetramethyl orthosilicate.

15. The process of claim 9, wherein said titanium dioxide sol is prepared by using an organic modifier added to a titanium dioxide precursor.

16. The process of claim 15, wherein said organic modifier is ketone and the molar ratio between titanium dioxide and ketone is from 1:10 to 1:1.

17. The process of claim 9, wherein said surfactant or surfactants are one or more members selected from the group consisting of long chain organic ammonium salt, amphiphilic block copolymer, cetyltrimethyl ammonium salt, and poly (ethylene oxide)-poly(propylene oxide)-poly(ethylene oxide).

18. The process of claim 9, wherein said surfactant or surfactants are a mixture of poly(ethylene oxide)-poly(propylene oxide) -poly(ethylene oxide) with ethylene oxide and propylene oxide.

19. The process of claim 9, wherein said surfactant is cetyltrimethyl ammonium bromide.

20. A method of increasing a chemical reaction, comprising using a TiO₂—SiO₂ aerogel of claim 1 as a catalyst.
